Data DescriptionDependent Variables

We define the random variable Y as the change in a specific outcome for U.S. natives, X as the Immigrant Inflow, and Z as the instrument for X. The sample $\{Y_c, X_c, Z_c\}_{c=1}^{722}$ consists of 722 CZs across the United States.

Due to the potential endogeneity of X, the structural model is proposed as follows:

$$Y_{c} = \alpha + \beta X_{c} + \mathbf{W}_{c}' \gamma + u_{c}$$
 (1)

$$X_{c} = \phi + \xi Z_{c} + \mathbf{W}_{c}' \theta + \nu_{c}$$
 (2)

$$\mathbb{E}\left[u_{c}|X_{c}\right]\neq0\tag{4}$$

$$Cov(X_c, Z_c) \neq 0 (5)$$

$$\mathbb{E}\left[u_{c}|Z_{c}\right] = \mathbb{E}\left[\nu_{c}|Z_{c}\right] = 0 \tag{6}$$

Where W is a vector of controls.

This model is estimated using 2SLS, correcting inference for heteroskedasticity and autocorrelation with clustered robust standard errors, grouped by state.

7

We are interested in evaluating the relationship between the instrument Z and the endogenous variable X, specifically $Cov(X_c, Z_c) \neq 0$, given the control variables W. To do so, we use the auxiliary regression:

$$r_{\mathsf{X},\mathsf{c}} = \psi r_{\mathsf{Z},\mathsf{c}} + \omega_{\mathsf{c}} \tag{7}$$

where $r_{X,C}$ and $r_{Z,C}$ are the orthogonal components of X and Z, respectively, defined as:

$$X_c = a_0 + W_c' a_1 + r_{X,c}$$
 (8)

$$Z_c = b_0 + \mathbf{W}_c' \mathbf{b_1} + r_{Z,c} \tag{9}$$

8

The null hypothesis that the instrument is irrelevant ($\psi=0$) is rejected if the $F_{partial}$ statistic exceeds 10¹. Alternatively, this can be tested using a χ^2 distribution with one degree of freedom², as we have a single endogenous variable and a single instrument.

The $F_{partial}$ statistic is defined as:

$$F_{partial} = \frac{R^2}{\frac{1-R^2}{n-1}} \tag{10}$$

where R^2 is the coefficient of determination from the auxiliary regression 7, and n is the number of observations, which in this case is 722.
